

Key Checking and Filtering Logic

Key Checking Logic:

This step verifies the presence of key in the second object.

Mechanism: It inspects each key from object1 and checks if object2 contains the exact same property.

Implementation: Executed using key in object2 on `set2.has(key)`.

Filtering Logic:

This step decides whether to include or discard the key based on the key check result.

If TRUE: The key passes the filter and is saved to the result object with obj1's value (`result[key] = obj1[key]`).

If FALSE: The key fails the filter and is skipped completely.

Logic Flow:
